

ROUND 2 · WEB DEVELOPMENT TASK

Project Tracker

A Kanban-style board for tracking projects through every stage

01 Concept

Build a Kanban-style board that lets someone track every project they're working on — personal, college, or freelance — and which stage each one is currently at, along with any notes about it. The tool mirrors real-world project management apps like Trello or Jira, and should be built as something that could genuinely be useful for managing a busy project workload.

02 Core Requirements

HTML + CSS ONLY · NO JAVASCRIPT NEEDED

These make up most of the evaluation and can be fully completed using only HTML and CSS.

1. Kanban Board Layout

Build the board structure using semantic HTML and CSS layout (Flexbox or Grid) with four columns representing stages: **Backlog** → **In Progress** → **Review** → **Completed**.

2. Project Cards

Hardcode a set of project cards (using the sample seed data below) placed inside their correct columns. Each card should display:

- Project name
- Category tag (Web, Design, Research, Hardware, etc.)
- Notes preview

3. Styling

- Color-coded category tags (e.g. Web = blue, Design = pink, Research = green)
- Clear visual distinction between the four columns
- A CSS hover effect on cards (e.g. a slight lift or shadow using `:hover`)

4. Responsive Layout

The board should adapt reasonably to smaller screens — for example, columns stacking vertically on mobile widths using CSS media queries.

5. Deployment

The finished page must be deployed live (e.g. GitHub Pages, Netlify, or Vercel) and the working link submitted along with your repository.

03 Bonus Features

· JAVASCRIPT / FRAMEWORKS

Everything below is a little more advanced and involves JavaScript. Attempt as much or as little as you're comfortable with — these differentiate stronger submissions but are not required to clear the task. Using a framework like React or Vue instead of vanilla JS is also welcome here.

TIER 1 Easy

- A working “Add Project” form that inserts a new card into the board
- Delete a card
- Empty-column placeholder message (e.g. “No projects yet”)

TIER 2 Medium

- “Move to next stage →” button that moves a card between columns
- Edit an existing card's fields (e.g. update notes as the project progresses)
- Search bar to filter by project name

TIER 3 Hard

- Persist all board data in localStorage, so refreshing the page keeps changes
- A small stats summary at the top (e.g. “5 Backlog, 2 In Progress, 1 Completed”)
- Actual drag-and-drop between columns (HTML5 Drag and Drop API or a library)

TIER 4 Stretch

- Dark mode toggle
- Sync board state across open browser tabs (using the Storage event listener)
- Rebuild the interactive version using React or Vue instead of vanilla JS

04 Sample Seed Data

Use this as your starting dataset to hardcode into your HTML cards, so you don't need to spend time inventing dummy data. If you attempt the JavaScript bonus features, you can also use this as your initial data source:

```
[
  {
    "id": 1,
    "project": "Portfolio Website",
    "category": "Web",
    "status": "In Progress",
    "notes": "Homepage layout done, working on projects section"
  },
  {
    "id": 2,
    "project": "Poster for Tech Fest",
    "category": "Design",
    "status": "Backlog",
    "notes": ""
  },
  {
    "id": 3,
    "project": "IoT Weather Station",
    "category": "Hardware",
    "status": "Review",
    "notes": "Sensor calibration pending"
  }
]
```

05 Constraints

Tech stack	HTML and CSS are the only mandatory requirement. JavaScript and frameworks (React/Vue) are optional — see Bonus Features.
Backend	Not required at any stage.
Submission	A GitHub repository link with your full source code, plus the live deployed link.

06 Evaluation Criteria

- **Layout & structure** — is the board correctly structured with semantic HTML and CSS layout?
- **Visual design** — are the columns, cards, and tags clear and well styled?
- **Responsiveness** — does the layout hold up on smaller screens?
- **Code organization** — is the code readable and reasonably structured?
- **Bonus features attempted** — how far up the JavaScript tiers did you go?
- **Git usage** — meaningful commit history is a plus.

Good luck — build something you'd actually want to use.
